Objectives

MedStar Health

Deformity considered acceptable for proximal humeral fractures has been subject to continuous debate. Neer's original paper tolerated up to 45° angulation. Recent studies have suggested deformities over 30° have unfavorable prognosis for post-traumatic arthritis.

The purpose of this study was to investigate the effects of humeral neck malunion on glenohumeral contact pressures.

Methods

Fifteen cadaveric shoulders (74.4y) were tested in a custom motorized frame (Fig 1). Shoulder was cycled from 0 to 60° at 1rpm. Muscle loading simulated active shoulder elevation: 80N on deltoid, 20N on each cuff muscles.

Contact pressures were measured using digital sensors (Tekscan) inserted into the glenoid and subacromial space (Fig 2).

A custom humerus plate with two perpendicular serial hinges simulated 15°, 30° and 45° malunion deformities in sagital and coronal planes (Fig 3).

Test conditions: intact, simple varus, valgus, antecurvatum and retrocurvatum, and combined deformities.

ANOVA/Fisher-LSD performed for each independent variable at P<0.05.

Results

Glenohumeral contact pressures were 13% (P=0.034) lower with varus 15°, 19% (P=0.005) with varus 30°, and 21% (P=0.003) with varus 45° malunion compared to intact.

Valgus 45° deformity increased glenohumeral pressure 17% (P=0.014) over intact. Valgus 30° increased 2%, and valgus 15° decreased 3%.

Antecurvatum 30° and 45° decreased contact pressures 14% (P=0.033) and 22% (P=0.001) respectively.

Retrocurvatum deformities kept glenohumeral pressures within 10% of intact values.

Subacromial Pressure (kPa) 120% Varus 45* P<0.0 4 113% P=0.027 1 103% Varus 15° -1 97% Varus-Antecurvatum 45°-45° -Antecurvatum 30°-30° 1 92% Retrocurvatum 45° /arus-Antecurvatum 15º-15º 87% 183% Retrocurvatum 15° Antecurvatum 15* + 82% Antecurvatum 45° → 82% P<0.05 Retrocurvatum 30° 181% Valgus 15* -+ 80% 478% Antecurvatum 30* Valgus-Retrocurvatum 15*-15* + 68% Retrocurvatum 45°-45° 64% P<0.001 63% Valgus 30* Valous-Retrocurvatum 30°-30° 6196 59% 300 100 200

Biplanar valgus-retrocurvatum 45°-45° deformity increased glenohumeral pressure 31% (P=0.001), while varusantecurvatum 45°-45° and 30°-30° decreased pressures 30% (P<0.001) and 29% (P<0.001) respectively.

All deformities except varus decreased subacromial pressures. Varus 30° increased subacromial pressure 13% (P=0.027), and varus 45° increased 20% (P<0.001) over intact.

Varus 30° deformity presented a loss of $5.8 \pm 1.0^{\circ}$ (P<0.001) in abduction arch, and varus 45° lost $15.4 \pm 1.7^{\circ}$ (P<0.001). No other malunion incurred in loss of range of motion.

Conclusions

Even small varus 15° deformity resulted in decreased glenohumeral contact pressure beyond 10% of the cut-off range of a normal shoulder, suggesting that patients may not tolerate it because of long-term infra-physiologic glenohumeral pressures result in degenerative changes due to inadequate nutrition to the cartilage.

Single plane deformities up to 30° in valgus and up to 45° retrocurvatum, and biplanar valgusretrocurvatum up to $30^{\circ}-30^{\circ}$ presented glenohumeral pressures within a ± 10% range of an intact shoulder, indicating that these deformities may be better tolerated than varus, antecurvatum and varus-antecurvatum malunions.
